Abstract: Causal and non-causal observability are discussed in this paper for nonlinear time-delay systems. By extending the Lie derivative for time-delay systems in the algebraic framework introduced by Xia et al. (2002), we present a canonical form and give sufficient condition in order to deal with causal and non-causal observations of state and unknown inputs of time-delay systems.

Keywords: Time-delay systems, Observability, Causality, Canonical form

1. INTRODUCTION

Observation or estimation is one of the most important problems in control theory. For nonlinear systems without delays, the observability problem has been exhaustively studied, and is characterized respectively by Hermann and Krener (1977); Sontag (1984); Krener (1985) from a differential point of view, and by Diop and Fliss (1991) from an algebraic point of view. For observable systems, many types of nonlinear observers were proposed, such as high-gain observer in Gauthier et al. (1992), algebraic observer in Barbot et al. (2007), sliding mode observer in Xiong and Saif (2001); Floquet and Barbot (2007) and so on.

However, unlike nonlinear systems without delays, the analysis of properties for time-delay system is more complicated (see the surveys in Sename (2001) and Richard (2003)). For linear time-delay systems, various aspects of the observability problem have been studied in the literature, by different methods such as functional analytic approach (Bhat and Koivo (1976)), algebraic approach (Brewer et al. (1986); Sontag (1976); Fliss and Monnier (1998)), and so on (Przyiuski and Sosnowski (1984)). The theory of non-commutative rings has been applied to analyze nonlinear time-delay systems firstly by Moog et al. (2000) for the disturbance decoupling problem of nonlinear time-delay system, and for observability of nonlinear time-delay systems with known inputs by Xia et al. (2002), for identifiability of parameter for nonlinear time-delay systems in Zhang et al. (2006), and for state elimination and delay identification of nonlinear time-delay systems by Anguelova and Wennberga (2008). In this algebraic framework, the left Ore ring of non-commutative polynomials defined over the field of meromorphic functions is used for the analysis of nonlinear time-delay systems, since the rank of a module over this ring is well defined and can be used to characterize controllability, observability and identifiability of nonlinear time-delay systems.

Concerning observer design for linear and nonlinear time-delay systems, see Boutayeb (2001); Pepe (2001); Germani et al. (2002); Darouach (2006); Seuret et al. (2007); Sename and Briat (2007); Ibrir (2009) and the references therein.

In this paper, based on the algebraic framework proposed by Xia et al. (2002), we give a general definition of observability for time-delay systems with unknown inputs. Then we generalize the notation of the Lie derivative for nonlinear systems with time-delay, and redefine the relative degree and observability indices for nonlinear time-delay systems by using the theory of non-commutative rings. After that a canonical form is derived and sufficient conditions are given to treat causal and non-causal observations of states and unknown inputs of time-delay systems.

2. ALGEBRAIC FRAMEWORK

Denote $\tau$ the basic time delay, and assume that the times delays are multiple times of $\tau$. Consider the following nonlinear time-delay system:

$$
\begin{align*}
\dot{x} &= f(x(t - i\tau)) + \sum_{j=0}^{s} g_j(x(t - j\tau))u(t - j\tau) \\
y &= h(x(t - i\tau)) = [h_1(x(t - i\tau)), \ldots, h_p(x(t - i\tau))]^T \\
x(t) &= \psi(t), u(t) = \phi(t), t \in [-s\tau, 0]
\end{align*}
$$

(1)

where $x \in W \subset \mathbb{R}^n$ denotes the state variables, $u = [u_1, \ldots, u_m]^T \in \mathbb{R}^m$ is the unknown admissible input, $y \in \mathbb{R}^p$ is the measurable output. Without loss of generality, we assume that $p \geq m$. And $i \in S_- = \{0, 1, \ldots, s\}$ is a finite set of constant time-delays, $f$, $g^j$ and $h$ are meromorphic
functions \(^1\), \(f(x(t-i\tau)) = f(x, x(t - \tau), \ldots, x(t - s\tau))\) and \(\psi : [-s\tau, 0) \to \mathbb{R}^n\) and \(\varphi : [-s\tau, 0) \to \mathbb{R}^n\) denote unknown continuous functions of initial conditions. In this work, it is assumed that \((1)\) with \(u = 0\) is locally observable, and for initial conditions \(\psi\) and \(\varphi\), \((1)\) admits a unique solution.

Based on the algebraic framework introduced in Xia et al. (2002), let \(\mathcal{K}\) be the field of meromorphic functions of a finite number of the variables from \(\{x_j(t-i\tau), j \in [1, n], i \in S_{-}\}\). With the standard differential operator \(d\), define the vector space \(\mathcal{E}\) over \(\mathcal{K}\):

\[
\mathcal{E} = \text{span}_{\mathcal{K}} \{d\xi : \xi \in \mathcal{K}\}
\]

which is the set of linear combinations of a finite number of one-forms from \(dx_j(t-i\tau)\) with row vector coefficients in \(\mathcal{K}\). For the sake of simplicity, we introduce backward time-shift operator \(\delta\), which means

\[
\delta^i \xi(t) = \xi(t-i\tau), \xi(t) \in \mathcal{K}, \text{ for } i \in \mathbb{Z}^+
\]

and

\[
\delta^i (a(t)d\xi(t)) = \delta^i a(t) \delta^i d\xi(t) = a(t-i\tau) d\xi(t-i\tau)
\]

for \(a(t)d\xi(t) \in \mathcal{E}\), and \(i \in \mathbb{Z}^+\).

Let \(\mathcal{K}(\delta)\) denote the set of polynomials of the form

\[
a(\delta) = a_0(t) + a_1(t) \delta + \cdots + a_r(t) \delta^r
\]

where \(a_i(t) \in \mathcal{K}\). The addition in \(\mathcal{K}(\delta)\) is defined as usual, but the multiplication is given as

\[
a(\delta)b(\delta) = \sum_{k=0}^r \sum_{i+j=k} a_i(t)b_j(t-i\tau)\delta^k
\]

Note that \(\mathcal{K}(\delta)\) satisfies the associative law and it is a non-commutative ring (see Xia et al. (2002)). However, it is proved that the ring \(\mathcal{K}(\delta)\) is a left Ore ring (Ježek, 1996; Xia et al. (2002)), which enables to define the rank of a module over this ring. Let \(\mathcal{M}\) denote the left module over \(\mathcal{K}(\delta)\):

\[
\mathcal{M} = \text{span}_{\mathcal{K}(\delta)} \{d\xi : \xi \in \mathcal{K}\}
\]

where \(\mathcal{K}(\delta)\) acts on \(d\xi\) according to (2) and (3).

With the definition of \(\mathcal{K}(\delta)\), (1) can be rewritten in a more compact form as follows:

\[
\begin{align*}
\dot{x} &= f(x, \delta) + \sum_{i=1}^m G_i u_i(t) \\
y &= h(x, \delta) \\
x(t) &= \psi(t), u(t) = \varphi(t), t \in [-s\tau, 0)
\end{align*}
\]

where \(f(x, \delta) = f(x(t - i\tau))\) and \(h(x, \delta) = h(x(t - i\tau))\) with entries belonging to \(\mathcal{K}\), \(G_i = \sum_{j=0}^n g_{ij} \delta^j\) with entries belonging to \(\mathcal{K}(\delta)\). It is assumed that \(\text{rank}_{\mathcal{K}(\delta)} \partial_h / \partial \delta = p\), which implies that \(h_1, \ldots, h_p\) are independent functions of \(x\) and its backward shifts.

3. NOTATIONS AND DEFINITIONS

Similar to observability definitions for nonlinear systems without delays given in Hermann and Krner (1977) and in Diop and Fliess (1991), a definition of observability for time-delay systems is given in Marquez-Martinez et al. (2002). A more generic definition is stated here as follows:

\[\text{Definition 1.}\] System (1) is locally observable if the state \(x(t) \in W \subset \mathbb{R}^n\) can be expressed as a function of the output and its derivatives with their backward and forward shifts as follows:

\[
x(t) = \alpha(y(t - j\tau), \ldots, y^{(k)}(t - j\tau))
\]

for \(j \in \mathbb{Z}\) and \(k \in \mathbb{Z}^+\). It is locally causally observable if (7) is satisfied for \(j \in \mathbb{Z}^+\) and \(k \in \mathbb{Z}^+\), and locally non-causally observable if (7) is satisfied for \(j \in \mathbb{Z}\) and \(k \in \mathbb{Z}^+\).

Following the same principle of Definition 1, we make the following definition for the unknown inputs.

\[\text{Definition 2.}\] The unknown input \(u(t)\) can be estimated if it can be written as a function of the derivatives of the output and its derivatives with backward and forward shifts, i.e.

\[
u(t) = \beta(y(t - j\tau), \ldots, y^{(k)}(t - j\tau))
\]

for \(j \in \mathbb{Z}\) and \(k \in \mathbb{Z}^+\). It can be causally estimated if (8) is satisfied for \(j \in \mathbb{Z}^+\) and \(k \in \mathbb{Z}^+\), and non-causally estimated if (8) is satisfied for \(j \in \mathbb{Z}\) and \(k \in \mathbb{Z}^+\).

The following example illustrates Definition 1 and 2.

\[\text{Example 1.}\] Consider the following system

\[
\begin{align*}
\dot{x}_1 &= x_2 + \delta x_1 \\
\dot{x}_2 &= \delta^2 x_2 - \delta x_3 \\
\dot{x}_3 &= \delta x_4 + \delta u_1 + \delta^4 u_2 \\
\dot{x}_4 &= \delta u_2 \\
y_1 &= x_1 \\
y_2 &= \delta x_4
\end{align*}
\]

A straightforward calculation gives

\[
\begin{align*}
x_1(t) &= y_1(t) \\
x_2(t) &= y_1(t) - y_1(t - \tau) \\
x_3(t) &= y_1(t - \tau) - y_1(t - 2\tau) - y_1(t + \tau) + y_1(t) \\
x_4(t) &= y_2(t + \tau)
\end{align*}
\]

and

\[
\begin{align*}
u_1(t) &= \dot{y}_1(t) - \dot{y}_1(t - \tau) - \ddot{y}_1(t + 2\tau) + \dot{y}_1(t + \tau) \\
u_2(t) &= \ddot{y}_1(t + 2\tau)
\end{align*}
\]

It can be seen that \(x_1\) and \(x_2\) are causally observable since they depend only on the outputs and their past values. However, \(x_3\), \(x_4\), \(u_1\), and \(u_2\) are not causally observable since they also depend on the future values of the outputs. So according to Definition 1 and 2, system (9) is observable, but the observability is not causal.

\[\text{Definition 3.}\] (Unimodular matrix) [Marquez-Martinez et al. (2002)] Matrix \(A \in \mathbb{K}^{n \times n}(\delta)\) is said to be unimodular over \(\mathcal{K}(\delta)\) if it has a left inverse \(A^{-1} \in \mathbb{K}^{n \times n}(\delta)\), such that \(A^{-1}A = \mathbb{I}_{n \times n}\).

\[\text{Remark 1.}\] An algorithm to check whether a matrix of \(\mathbb{K}^{n \times n}(\delta)\) is unimodular is stated in Marquez-Martinez et al. (2002).

\[\text{Definition 4.}\] (Change of coordinate) [Marquez-Martinez et al. (2002)] For system (1), \(z = \phi(\delta, x) \in \mathbb{K}^{n \times 1}\) is a causal change of coordinate over \(\mathcal{K}\) for (1) if there exist locally a function \(\phi^{-1} \in \mathbb{K}^{n \times 1}\) and some constants \(c_1, \ldots, c_n \in N\) such that

\[
\text{diag}(\delta^{n})x = \phi^{-1}(\delta, z).
\]

The change of coordinate is bicausal over \(\mathcal{K}\) if \(\max\{c_i\} = 0\), i.e. \(x = \phi^{-1}(\delta, z)\).

Note that the relative degree for nonlinear systems without delays is well defined via the Lie derivative (see Isidori}
If for \(1 \leq k \leq u\) (2000).

system is equivalent to the definition given in Moog et al. (2002), from non-commutative rings point of view.

Let \(f(x(t-j\tau))\) and \(h(x(t-j\tau))\) for \(0 \leq j \leq s\) respectively be an \(n\) and \(p\) dimensional vector with entries \(f_r \in \mathcal{K}\) for \(1 \leq r \leq n\) and \(h_i \in \mathcal{K}\) for \(1 \leq i \leq p\). Let
\[
\frac{\partial h_i}{\partial x} = \left[\frac{\partial h_{i1}}{\partial x_1}, \ldots, \frac{\partial h_{in}}{\partial x_n}\right] \in \mathcal{K}^{1 \times n}(\delta) \tag{10}
\]
where for \(1 \leq r \leq n:\)
\[
\frac{\partial h_i}{\partial x_r} = \sum_{j=0}^{s} \frac{\partial h_i}{\partial x_r(t-j\tau)} \delta^j \in \mathcal{K}(\delta)
\]
then the Lie derivative for nonlinear systems without delays can be extended to nonlinear time-delay systems in the framework of Xia et al. (2002) as follows
\[
L_f h_i = \frac{\partial h_i}{\partial x} (f) = \sum_{r=1}^{n} \sum_{j=0}^{s} \frac{\partial h_i}{\partial x_r(t-j\tau)} \delta^j (f_r) \in \mathcal{K} \tag{11}
\]
For \(j = 0\), (11) is the classical definition of the Lie derivative of \(h\) along \(f\). For \(h_i \in \mathcal{K}\), define
\[
L_G h_i = \frac{\partial h_i}{\partial x} (G_i) \in \mathcal{K}(\delta)
\]
By the above definition of Lie derivative, we can define the relative degree in the following way:

Definition 5. (Relative degree) System (6) has relative degree \((\nu_1, \ldots, \nu_p)\) in an open set \(W \subseteq \mathbb{R}^n\) if, for \(1 \leq i \leq p\), the following conditions are satisfied:

1. for all \(x \in W\), \(L_G^j L_f^j h_i = 0\), for all \(1 \leq j \leq m\) and \(0 \leq r < \nu_i - 1\);
2. there exists \(x \in W\) such that \(\exists j \in [1, m]\), \(L_G^j L_f^j h_i \neq 0\).

If for \(1 \leq i \leq p\), (1) is satisfied for all \(r \geq 0\), then we set \(\nu_i = \infty\).

Remark 2. This definition of relative degree for time-delay system is equivalent to the definition given in Moog et al. (2000).

Since (6) is locally observable when \(u = 0\), then one can define, for (6), the so-called observability indices introduced in Krener (1985). Let
\[
\mathcal{F}_k := \text{span}_{\mathcal{K}(\delta)} \{d_k, d_L f h_1, \ldots, d_L^{k-1} h_1\}
\]
for \(1 \leq k \leq n\). And it was shown that the filtration of \(\mathcal{K}(\delta)\)-module satisfies \(\mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \subset \mathcal{F}_n\), then we define \(d_k = \text{rank}_{\mathcal{K}(\delta)} \mathcal{F}_k - \text{rank}_{\mathcal{K}(\delta)} \mathcal{F}_{k-1}\), for \(2 \leq k \leq n\). Let \(k_i = \text{card} \{d_k \geq i, 1 \leq k \leq n\}\), then \((k_1, \ldots, k_p)\) are the observability indices, and \(\sum_{i=1}^{p} k_i = n\) since it is assumed that (6) is observable with \(u = 0\). Reordering, if necessary, the output components of (6), such that
\[
\frac{\partial}{\partial x} \left[ h_1, L_f h_1, \ldots, L_f^{k_1-1} h_1, \ldots, h_p, L_f h_p, \ldots, L_f^{k_p-1} h_p \right]^T = \rho_i
\]
where for \(1 \leq i \leq p\), denote \(k_i\) the observability indices and \(\nu_i\) the relative degree index for \((h_1, \ldots, h_p)\) are well defined, but the order may be not unique.

4. CANONICAL FORM AND CAUSAL OBSERVABILITY

After having defined the relative degree and observability indices via the extended Lie derivative for nonlinear time-delay systems in the framework of non-commutative rings, we are ready to state the following theorem.

Theorem 1. For \(1 \leq i \leq p\), denote \(k_i\) the observability indices and \(\nu_i\) the relative degree index for \(y_i\) of (6), and note \(\rho_i = \min \{\nu_i, k_i\}\). Then there exists a change of coordinate \(\phi(x, \delta)\) \(\in \mathcal{K}^{n \times 1}\), such that (6) can be transformed into the following form:
\[
\dot{z}_i = A_i z_i + B_i V_i
\]
\[
\dot{\xi} = \alpha(z, \xi, \delta) + \beta(z, \xi, \delta) u
\]
\[
y_i = C_i z_i
\]
where
\[
z_i = \left( h_i, \ldots, L_f^{\rho_i-1} h_i \right)^T \in \mathcal{K}^{n \times 1}
\]
\[
A_i = \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 0 \end{pmatrix} \in \mathbb{R}^{n \times \rho_i}, B_i = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix} \in \mathbb{R}^{n \times 1},
\]
\[
V_i = L_f^{\rho_i} h_i(x, \delta) + \sum_{j=1}^{m} L_G^j L_f^{j-1} h_i(x, \delta) u_j \in \mathcal{K}
\]
\[
\alpha \in \mathcal{K}^{1 \times 1}, \beta \in \mathcal{K}^{1 \times 1}(\delta) \quad \text{with} \quad l = n - \sum_{j=1}^{p} \rho_j
\]
\[
C_i = (1, 0, \ldots, 0) \in \mathbb{R}^{1 \times \rho_i}
\]
Moreover if \(k_i < \nu_i\), one has \(V_i = L_f^{\rho_i} h_i = L_f^{\rho_i} h_i\).

Proof 1. According to the definition of \(k_i\), for \(1 \leq i \leq p\), one has
\[
\text{rank}_{\mathcal{K}(\delta)} \left[ h_i, L_f h_i, \ldots, L_f^{k_i-1} h_i \right]^T = k_i
\]
since \(\rho_i = \min \{k_i, \nu_i\}\), one gets
\[
\text{rank}_{\mathcal{K}(\delta)} \left[ h_i, L_f h_i, \ldots, L_f^{\rho_i-1} h_i \right]^T = \rho_i
\]
which implies that the components
\[
z_i = \left( h_i, \ldots, L_f^{\rho_i-1} h_i \right)^T
\]
are linearly independent over $\mathcal{K}(\delta)$. Denote
\[ z = (z_1^T, \ldots, z_p^T)^T \in \mathcal{K}^{n-l}, \text{ with } l = \sum_{j=1}^{p} \rho_j, \]
and choose $l$ variables $\xi \in \mathcal{K}^l$, such that $(z^T, \xi^T)^T = \phi(x, \delta) \in \mathcal{K}^n$ is a well-defined change of coordinate. Then for $1 \leq i \leq p$ and $1 \leq j \leq \rho_i - 1$, one has
\[
\dot{z}_{i,j} = z_{i,j+1}
\]
\[
\dot{z}_{i,\rho_i} = L_f^{\rho_i} h_i + \sum_{j=1}^{m} L_{G_j} L_f^{\rho_i-1} h_i(x, \delta) u_j
\]
y_i = z_{i,1} = C_i z_i
and
\[
\dot{\xi} = \alpha(z, \xi, \delta) + \beta(z, \xi, \delta) u
\]
which means (6) can be transformed into form (12-14).
Moreover, according to the definition of $\nu_i$, for all $1 \leq j \leq m$ and $0 \leq r < \nu_i - 1$, one has
\[
L_G L_f^{\rho_i-1} h_i = \frac{\partial}{\partial x} \left( L_f^{\rho_i} h_i \right) \text{ for } (G_j) = 0
\]
\[
L_G L_f^{\rho_i-1} h_i = \frac{\partial}{\partial x} \left( L_f^{\rho_i} h_i \right) \neq 0
\]
Hence, if $k_i < \nu_i$, then $\rho_i = k_i$ and one has $L_{G_j} L_f^{k_i-1} h_i(x, \delta) = 0$, which yields $V_i = L_f^{\rho_i} h_i = L_f^{k_i} h_i$. ■

Remark 3. For (12-14), one can find observers in the literature (Xiong and Saif (2001); Floquet and Barbot (2007)) such that $z_i$ for $1 \leq i \leq p$ can be estimated in finite time due to the triangular structure. In addition, one can also obtain the information $V_i = y_i^{(\rho_i)}$ in finite time.

For (12), note
\[ H(x, \delta) = \Psi(x, \delta) + \Gamma(x, \delta) u \tag{15} \]
with
\[ H(x, \delta) = \begin{pmatrix} h_1^{(\nu_1)} \\ \vdots \\ h_p^{(\rho_p)} \end{pmatrix}, \Psi(x, \delta) = \begin{pmatrix} L_f^{\rho_1} h_1 \\ \vdots \\ L_f^{\rho_p} h_p \end{pmatrix} \]
and
\[ \Gamma(x, \delta) = \begin{pmatrix} L_G L_f^{\rho_1-1} h_1 & \cdots & L_{G_m} L_f^{\rho_1-1} h_1 \\ \vdots & \ddots & \vdots \\ L_G L_f^{\rho_p-1} h_p & \cdots & L_{G_m} L_f^{\rho_p-1} h_p \end{pmatrix} \]
where $H(x, \delta) \in \mathcal{K}^{n+1}$, $\Psi(x, \delta) \in \mathcal{K}^{p+1}$ and $\Gamma(x, \delta) \in \mathcal{K}^{p\times m}(\delta)$. And for (6), let denote $\Phi$ the observable space from its outputs:
\[ \Phi = \{dh_1, \ldots, dL_f^{\rho_1-1} h_1, \ldots, dh_p, \ldots, dL_f^{\rho_p-1} h_p\} \tag{16} \]
then we have the following theorem.

Theorem 2. For system (6) with outputs $(y_1, \ldots, y_p)$ and corresponding $(\rho_1, \ldots, \rho_p)$ with $\rho_i = \min \{k_i, \nu_i\}$ where $k_i$ and $\nu_i$ are respectively the associated observability indices and the relative degree, if
\[ \text{rank}_{\mathcal{K}(\delta)} \Phi = n \]
where $\Phi$ defined in (16), then there exists a change of coordinate $\phi(x, \delta)$ such that (6) can be transformed into (12-14) with $\xi = 0$.
Moreover, if the change of coordinate is bicausal over $\mathcal{K}$, then the state $z(t)$ of (6) is causally observable.
For the matrix $\Gamma \in \mathcal{K}^{m\times m}(\delta)$ where $m \leq p$, if
\[ \text{rank}_{\mathcal{K}(\delta)} \Gamma = m \]
then there exists a matrix $Q \in \mathcal{K}^{p\times p}(\delta)$ such that
\[ Q \Gamma = \begin{bmatrix} \bar{\Gamma} \\ 0 \end{bmatrix} \]
where $\bar{\Gamma} \in \mathcal{K}^{m\times m}(\delta)$ has full row rank $m$. Moreover, if $\Gamma \in \mathcal{K}^{m\times m}(\delta)$ is also unimodular over $\mathcal{K}(\delta)$, then the unknown input $u(t)$ of (6) can be causally estimated as well.

Proof 2. According to Theorem 1, (6) can be transformed into (12-14) by $(z, \xi) = \phi(x, \delta)$. Hence, if $\text{rank}_{\mathcal{K}(\delta)} \Phi = n$, where $\Phi$ defined in (16), then one has $\sum_{j=1}^{m} \rho_j = n$, which implies (6) can be transformed into (12-14) with $\xi = 0$ and the change of coordinate is given by $z = \phi(x, \delta)$ where $z = (z_1^T, \ldots, z_p^T)^T$ and $z_i = (h_i, \ldots, L_f^{\rho_i-1} h_i)^T$.
Moreover, if $\phi(x, \delta) \in \mathcal{K}^{n\times 1}$ is bicausal over $\mathcal{K}$, one can write $x$ as a function of $y_i$, its derivative and backward shift, which implies state $x$ is causally observable.

Concerning the reconstruction of unknown inputs, rewrite (15) as follows
\[ \Gamma u = H(x, \delta) - \Psi(x, \delta) = \Upsilon(x, \delta) \tag{17} \]
Since $\text{rank}_{\mathcal{K}(\delta)} \Phi = n$ and $x$ is causally observable, then $\Upsilon(x, \delta)$ is a vector of known meromorphic functions belonging to $\mathcal{K}$.

According to Lemma 4 in Marquez-Martinez and Moog (2007), for any matrix $\Gamma \in \mathcal{K}^{p\times m}$, if $\text{rank}_{\mathcal{K}(\delta)} \Gamma = m$, by some necessary manipulations, one can always find at least a matrix $Q \in \mathcal{K}^{p\times p}$ such that $Q \Gamma = \begin{bmatrix} \Gamma \\ 0 \end{bmatrix}$ where $\bar{\Gamma} \in \mathcal{K}^{m\times m}(\delta)$ has full row rank $m$. Thus, if $\bar{\Gamma} \in \mathcal{K}^{m\times m}(\delta)$ is unimodular over $\mathcal{K}(\delta)$, then there exists a matrix $\Gamma^{-1} \in \mathcal{K}^{m\times m}(\delta)$ such that
\[ \begin{bmatrix} \Gamma^{-1} \\ 0 \end{bmatrix} Q \Gamma = I_{m\times m} \]
and
\[ u = [\bar{\Gamma}^{-1} \ 0] Q \Gamma \]
Since $\bar{\Gamma}^{-1} \in \mathcal{K}^{m\times m}(\delta)$, $Q \in \mathcal{K}^{p\times p}$ and $\Upsilon \in \mathcal{K}^{p\times 1}$, then $u$ of (6) is also causally observable. ■

Example 2. Consider the following system:
\[
\begin{cases}
x_1 = -u_1 + x_2 \\
x_2 = -3x_3 + u_1 \\
x_3 = 2x_2 + u_1 + u_2 \\
x_4 = -x_4 + 2dx_4/3 \\
y_1 = x_1 \\
y_2 = x_3 \\
y_3 = x_4
\end{cases}
\tag{18}
\]
One can check that $\nu_1 = k_1 = 2$, $\nu_2 = k_2 = 1$, $\nu_3 = \infty$ and $k_3 = 1$, then one gets $\rho_1 = 2$, $\rho_2 = 1$ and $\rho_3 = 1$. According to (16), one has
\[
\Phi = \{dh_1, dL_f h_1, dh_2, dh_3\} = \{dx_1, -\delta x_1 + dx_2, dx_3, dx_4\} \]
Since $rank_{\mathcal{K}(\delta)}\Phi = 4$, this gives the following change of coordinate for (18):

\[ z = \phi(x, \delta) = (x_1, x_2 - \delta x_1, x_3, x_4)^T \]

One can check that the change of coordinate is bicausal over $\mathcal{K}$, since $x$ can be expressed causally by $z$ as follows:

\[ x = \phi^{-1} = (z_1, \delta z_1 + z_2, z_3, z_4)^T \]

Thus the state of (18) is causally observable and a straightforward computation gives

\[
\begin{align*}
  x_1(t) &= y_1(t) \\
  x_2(t) &= y_1(t - \tau) + y_1(t) \\
  x_3(t) &= y_2(t) \\
  x_4(t) &= y_3(t)
\end{align*}
\]

Moreover, one has $\Gamma = \begin{pmatrix} 1 & 0 \\ \delta & 1 \end{pmatrix}$, which gives $rank_{\mathcal{K}(\delta)}\Gamma = m = 2$. Thus $\Gamma$ is unimodular over $\mathcal{K}(\delta)$, since one can find $\Gamma^{-1} = \begin{pmatrix} 1 & 0 \\ -\delta & 1 \end{pmatrix}$, such that $\Gamma^{-1} \Gamma = I_{2 \times 2}$. According to Theorem 2, the unknown inputs $u_1$ and $u_2$ are also causally observable. One can easily obtain the following equations:

\[
\begin{align*}
  u_1(t) &= \dot{y}_1(t - \tau) + \dot{y}_1(t) + y_2(t - \tau) \\
  u_2(t) &= \dot{y}_2(t) - y_1(t - \tau) - \dot{y}_1(t - 2\tau) \\
  \dot{y}_1(t) &= y_2(t - 2\tau)
\end{align*}
\]

Let us remark that it is the bicausal change of coordinate which makes the state of system causally observable. And it is the unimodular characteristic of $\Gamma$ over $\mathcal{K}(\delta)$ which guarantees the causal reconstruction of unknown inputs. The next section is devoted to dealing with the non-causal case.

## 5. NON-CAUSAL OBSERVABILITY

In order to treat the non-causal case, let introduce the forward time-shift operator $\nabla$, which is similar to the backward time-shift operator $\delta$ defined in Section 2:

\[ \nabla f(t) = f(t + \tau) \]

\[ \nabla^i \delta^j f(t) = \delta^j \nabla^i f(t) = f(t - (j - i)\tau) \]

for $i, j \in N$

Following the same principle of Section 2, denote $\tilde{\mathcal{K}}$ the field of meromorphic functions of a finite number of variables from $\{x_j(t - i\tau), j \in [1, n], i \in S\}$ where $S = \{1, \ldots, s\}$ is a finite set of constant and one has $\mathcal{K} \subseteq \tilde{\mathcal{K}}$. Denote $\tilde{\mathcal{K}}(\delta, \nabla)$ the set of polynomials of the form as follows:

\[
a(\delta, \nabla) = a_{\tau_1} \nabla^{\tau_1} + \cdots + \tilde{a}_1 \nabla + a_0(t) + a_1(t) \delta + \cdots + a_{\tau_n}(t) \delta^{\tau_n} \]

where $a_1(t)$ and $\tilde{a}_1(t)$ belonging to $\tilde{\mathcal{K}}$. Let keep the same definition of addition for $\tilde{\mathcal{K}}(\delta, \nabla)$, and the multiplication is given as follows:

\[
a(\delta, \nabla) b(\delta, \nabla) = \sum_{i=0}^{r_b} \sum_{j=0}^{r_a} a_i b_j \delta^{i+j} + \sum_{i=0}^{r_b} \sum_{j=1}^{r_a} a_i b_j \delta^i \nabla^j + \sum_{i=1}^{r_b} \sum_{j=0}^{r_a} a_i \nabla^i b_j \delta^{i+j} + \sum_{i=1}^{r_b} \sum_{j=1}^{r_a} a_i \nabla^i b_j \nabla^{i+j} \]

(20)

It is clear that $\mathcal{K}(\delta) \subseteq \tilde{\mathcal{K}}(\delta, \nabla)$ and the ring $\tilde{\mathcal{K}}(\delta, \nabla)$ possesses the same properties as $\mathcal{K}(\delta)$. Thus a module can be also defined over $\tilde{\mathcal{K}}(\delta, \nabla)$:

\[ \mathcal{M} = \text{span}_{\tilde{\mathcal{K}}(\delta, \nabla)} \{ \xi \mid \xi \in \tilde{\mathcal{K}} \} \]

Given the above definitions, Theorem 2 can then be extended as follows in order to deal with non-causal observability for nonlinear time-delay systems.

**Theorem 3.** For system (6) with outputs $(y_1, \ldots, y_p)$ and corresponding $(\rho_1, \ldots, \rho_p)$, if

\[ rank_{\mathcal{K}(\delta)}\Phi = n \]

where $\Phi$ defined in (16), then there exists a change of coordinate $z = \phi(x, \delta)$ such that (6) can be transformed into (12-14) with $\xi = 0$.

Moreover, if the change of coordinate $z = \phi(x, \delta)$ is bicausal over $\tilde{\mathcal{K}}$, then the state $x(t)$ of (6) is at least non-causally observable.

For the deduced matrix $\Gamma$ with $rank_{\mathcal{K}(\delta)}\Gamma = m$, one can obtain a matrix $\bar{\Gamma} \in \mathcal{K}^{m \times m}(\delta)$ which has full row rank $m$. If $\bar{\Gamma}$ is unimodular over $\mathcal{K}(\delta, \nabla)$, then the unknown input $u(t)$ of (6) can be at least non-causally estimated as well.

**Proof 3.** If the change of coordinate $z = \phi(x, \delta) \in \mathcal{K}^{n \times 1}$ is bicausal over $\tilde{\mathcal{K}}$, then there exist $\phi^{-1} \in \mathcal{K}^{n \times 1}$ and certain $c_1, \ldots, c_n$ such that

\[ T x = \phi^{-1}(z, \delta) \]

where $T = \text{diag}(\delta^{c_1}, \ldots, \delta^{c_n})$. Thus one can define the matrix $T^{-1} = \text{diag}(\nabla^{c_1}, \ldots, \nabla^{c_n}) \in \mathcal{K}^{n \times n}(\delta, \nabla)$, such that

\[ x = T^{-1} \phi^{-1}(z, \delta) \]

which means $x$ is at least non-causally observable.

For the estimation of $u(t)$, if $\bar{\Gamma}$ is unimodular over $\mathcal{K}(\delta, \nabla)$, then following the same procedure of Theorem 2, one gets

\[ u = \begin{bmatrix} \bar{\Gamma}^{-1} & 0 \\ Q \end{bmatrix} \Psi \]

In this case, since $\bar{\Gamma}^{-1} \in \mathcal{K}(\delta, \nabla)$, $Q \in \mathcal{K}^{p \times p}(\delta)$ and $\Psi \in \mathcal{K}^{p \times 1}$, then $u(t)$ of (6) is at least non-causally observable.

**Remark 4.** Non-causal observations of the state and the unknown inputs are in some case very useful. Because of the non causality, $x$ and $u$ are estimated with some known delays. Many proposed delay feedback control methods can then be applied for stabilizing nonlinear time-delay systems (Fridman et al. (2003), Sename (2007)). At the other hand, other applications, such as cryptography based on chaotic system, need not the real time estimation, hence non-causal observations can still play an important role in those applications.

## 6. CONCLUSION

This paper introduced a new generic definition of observability for time-delay systems with unknown inputs, covering causal and non-causal observability. Then the relative degree and observability indices for nonlinear time-delay systems were defined based on the notion of the Lie derivation in the framework of non-commutative rings. After that, we introduced a canonical form for time-delay systems, and sufficient conditions were given to guarantee the causal and non-causal observations of states and unknown inputs of time-delay systems.
